Why graphics?

1. To explore data (interactively)
2. To communicate data & preliminary insights with collaborators
3. To publish results

Goals for this lecture

- Review base R plotting
- Understand the **grammar of graphics** concept
- Introduce ggplot2's ggplot function
- See how to plot 1D, 2D, 3-5D data and understand faceting
- Visualisation for quickly viewing large datasets and discover large-scale trends (e.g. batch effects)
- Use colours like a pro

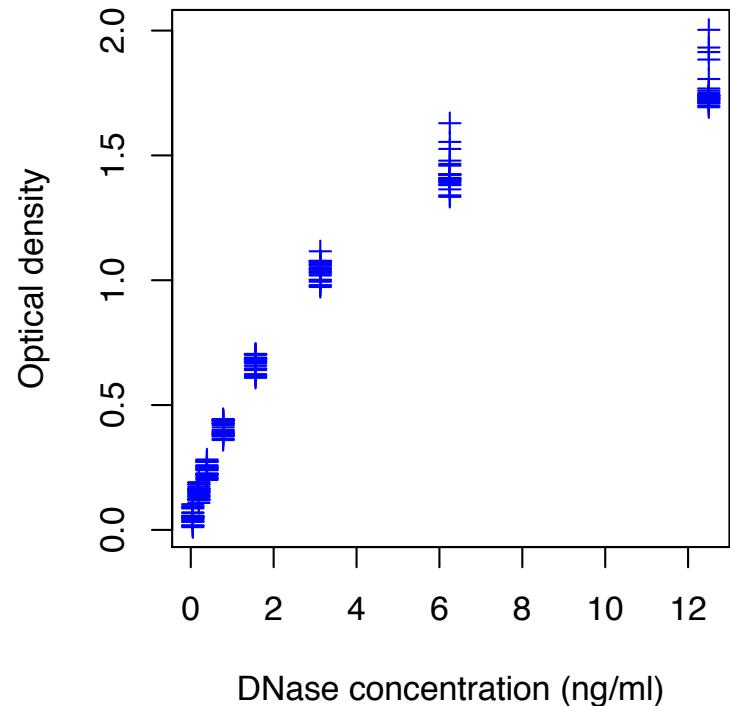

base R plotting

Canvas model: a series of instructions that sequentially fill the plotting canvas

```
head(DNase)

##   Run   conc density
## 1  1 0.0488  0.017
## 2  1 0.0488  0.018
## 3  1 0.1953  0.121
## 4  1 0.1953  0.124
## 5  1 0.3906  0.206
## 6  1 0.3906  0.215
```

```
plot(DNase$conc, DNase$density,
ylab = attr(DNase, "labels")$y,
xlab = paste(attr(DNase, "labels")$x, attr(DNase, "units")$x),
pch = 3, col = "blue")
```

Drawbacks:

- Layout choices have to be made at the beginning with no overview over what may still be coming
- Different functions for different plot types, with different interfaces
- Many routine tasks require a lot of ‘boilerplate’ code
- No concept of facets / lattices
- No concept of viewports, only a single global coordinate system
- Default colours are poor
- Resizing often leads to unsatisfactory results

```
head(DNase)
##   Run
## 1  0
## 2  0
## 3  0
## 4  0
## 5  0
## 6  0

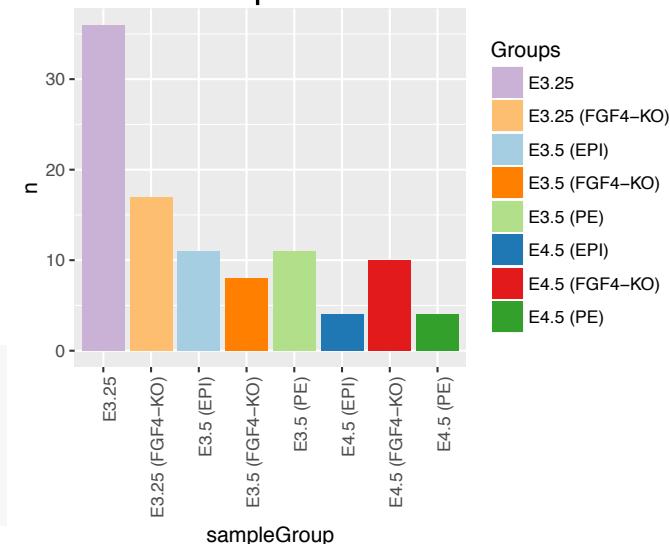

plot(DNase)
ylab = at
xlab = pas
pch = 3, c
```

The grammar of graphics

The components of ggplot2's grammar of graphics are

- one or more datasets ("noun"),
- one or more geometric objects that serve as the visual representations of the data, for instance, points, lines, rectangles, contours ("verb"),
- descriptions of how the variables in the data are mapped to visual properties (aesthetics) of the geometric objects, and an associated scale (e.g. linear, logarithmic, rank),
- one or more coordinate systems,
- statistical summarization rules (e.g. line fit, binning),
- a facet specification, i.e. the use of multiple similar subplots to look at subsets of the same data,
- optional parameters for layout and rendering, e.g. text size, font, alignment; legend positions

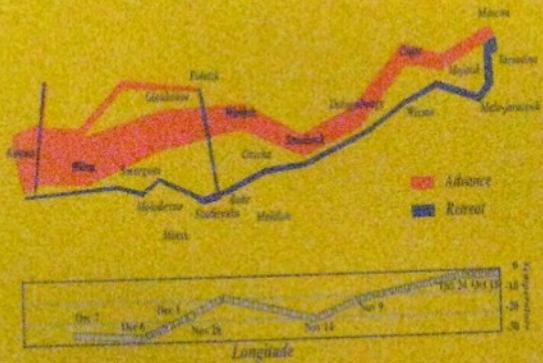

```
ggplot(groups, aes(x = sampleGroup, y = n, fill = sampleGroup)) +  
  geom_bar(stat = "identity") +  
  scale_fill_manual(values = groupColour, name = "Groups") +  
  theme(axis.text.x = element_text(angle = 90, hjust = 1))
```

Graphical Statistics, 2010

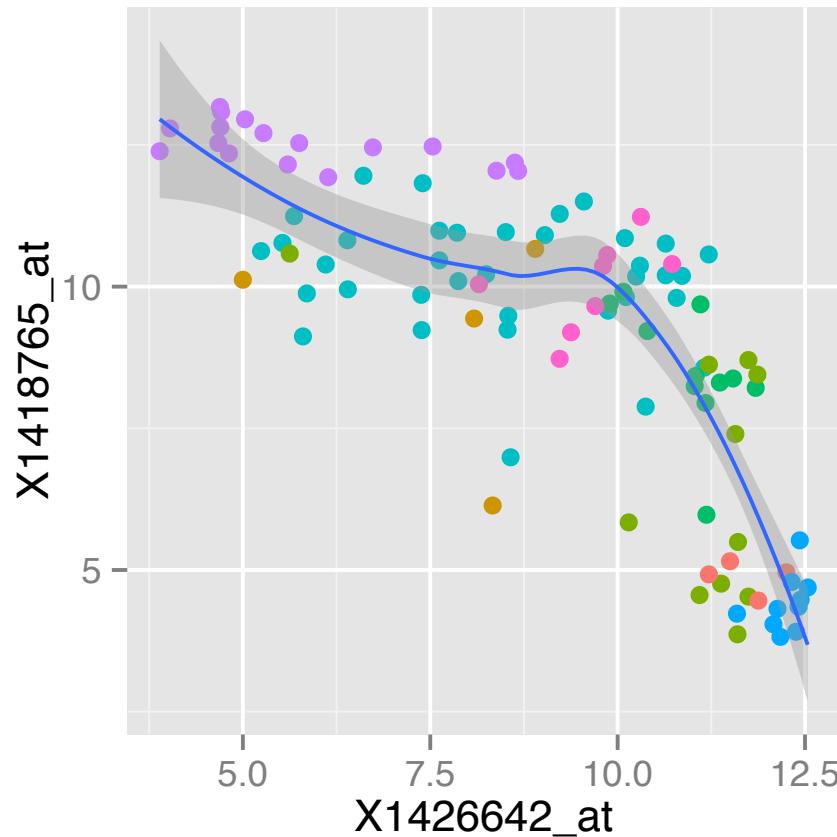

Volume 19, Number 1, Pages 3–28

DOI: [10.1198/jcgs.2009.07098](https://doi.org/10.1198/jcgs.2009.07098)

1999

Layers

```
ggplot( dftx, aes( x = X1426642_at, y = X1418765_at ) ) +  
  geom_point( aes( colour = sampleColour), shape = 19 ) +  
  geom_smooth( method = "loess" ) +  
  scale_colour_discrete( guide = FALSE )
```

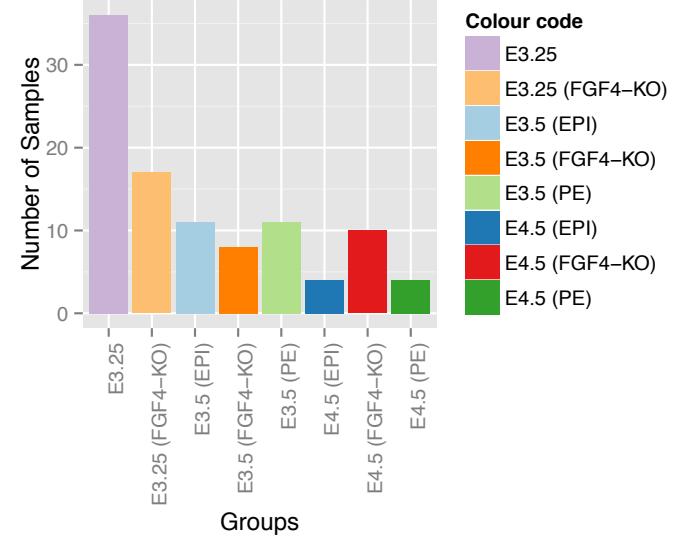

A more complex example: themes

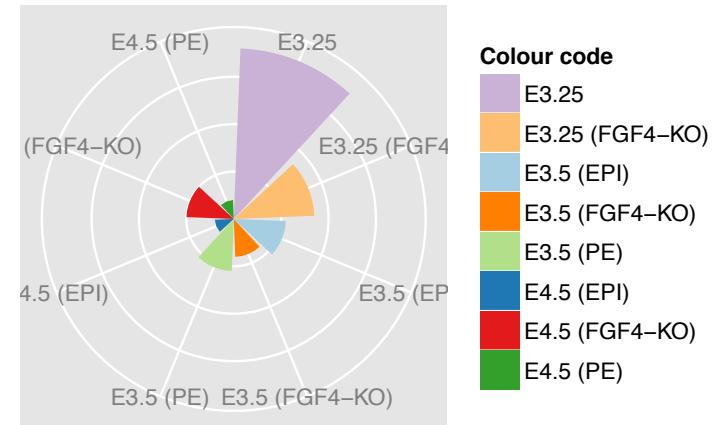

```
pb <- ggplot(data.frame(  
  name = names(groupSize),  
  size = as.vector(groupSize)),  
  aes(x = name, y = size))
```

No geom defined yet!

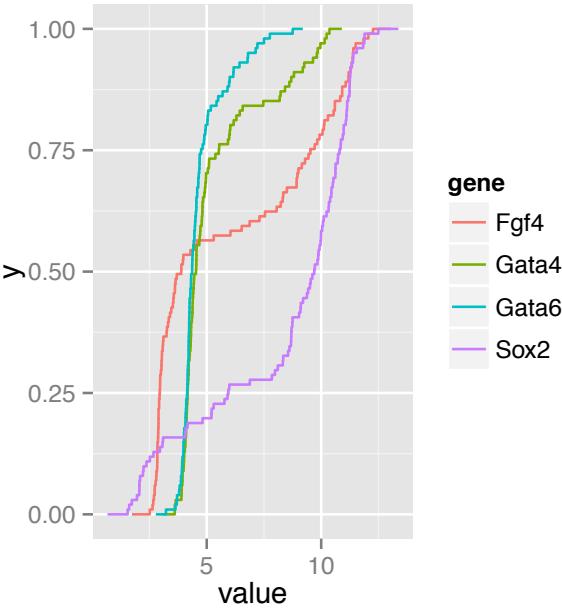

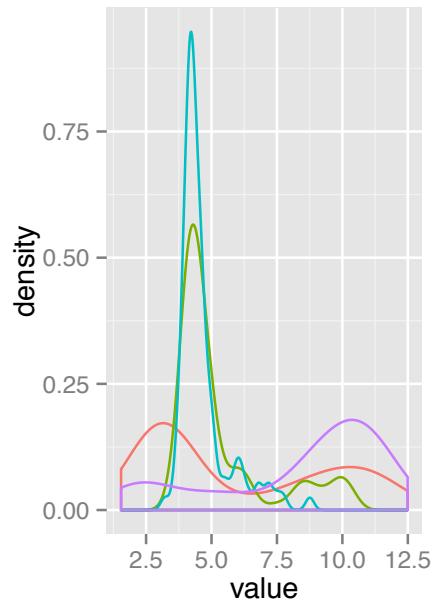

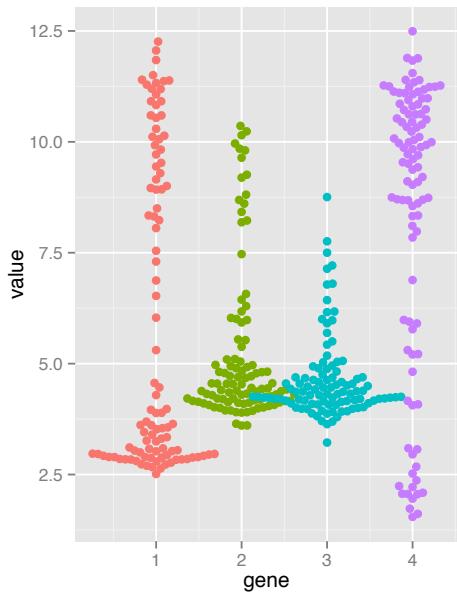

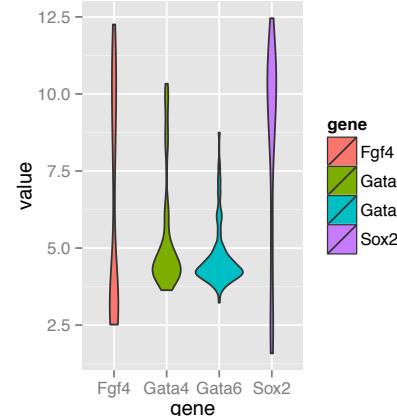

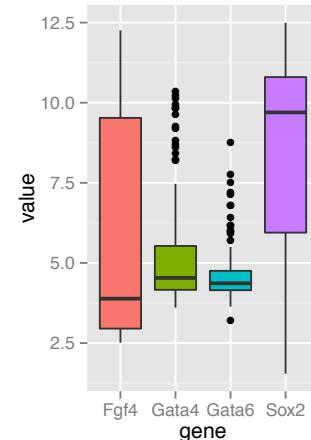

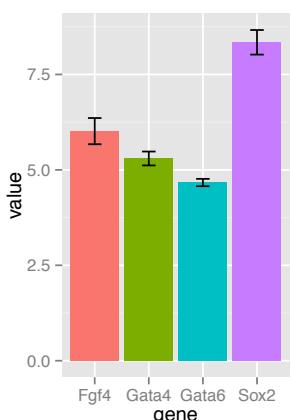

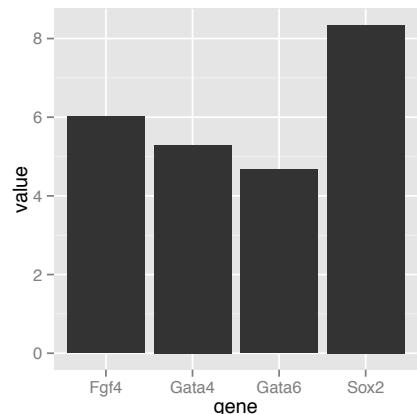

```
pb <- pb + geom_bar(stat = "identity") +  
  aes(fill = name) +  
  scale_fill_manual(values = groupColour, name = "Colour code") +  
  theme(axis.text.x = element_text(angle = 90, hjust = 1)) +  
  xlab("Groups") + ylab("Number of Samples")
```

```
pb.polar <- pb + coord_polar() +  
  theme(axis.text.x = element_text(angle = 0, hjust = 1),  
        axis.text.y = element_blank(),  
        axis.ticks = element_blank()) +  
  xlab("") + ylab("")  
pb.polar
```

Visualizing distributions in 1D

Discussion of 1D plot types

[Boxplot](#) makes sense for unimodal distributions

[Histogram](#) requires definition of bins (width, positions) and can create visual artifacts esp. if the number of data points is not large

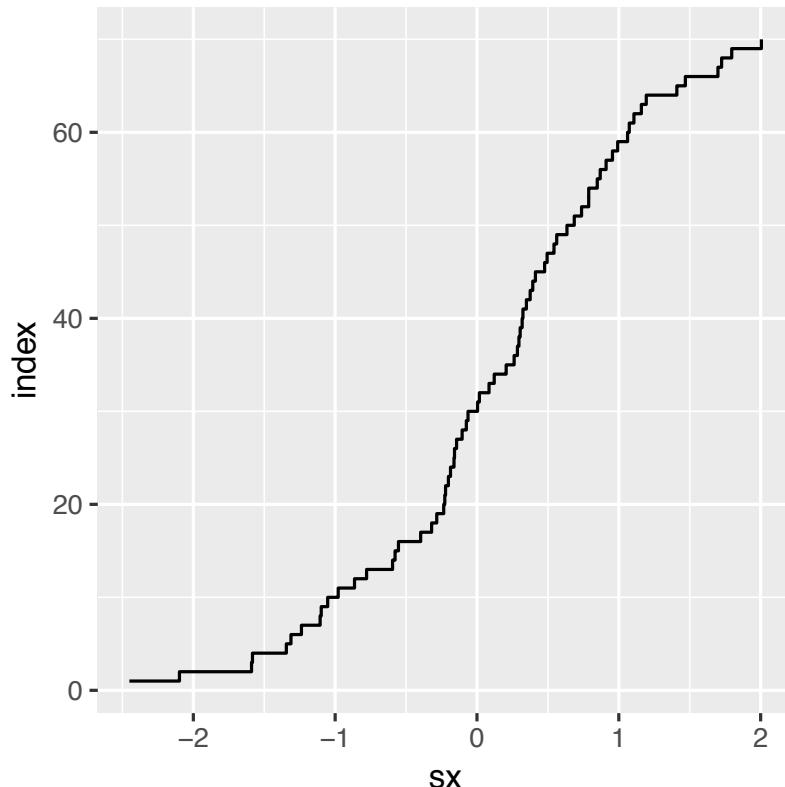

[Density](#) requires the choice of bandwidth; obscures the sample size (i.e. the uncertainty of the estimate)

[ecdf](#) does not have these problems; but is more abstract and interpretation requires more training. Good for reading off quantiles and shifts in location in comparative plots; OK for detecting differences in scale; less good for detecting multimodality.

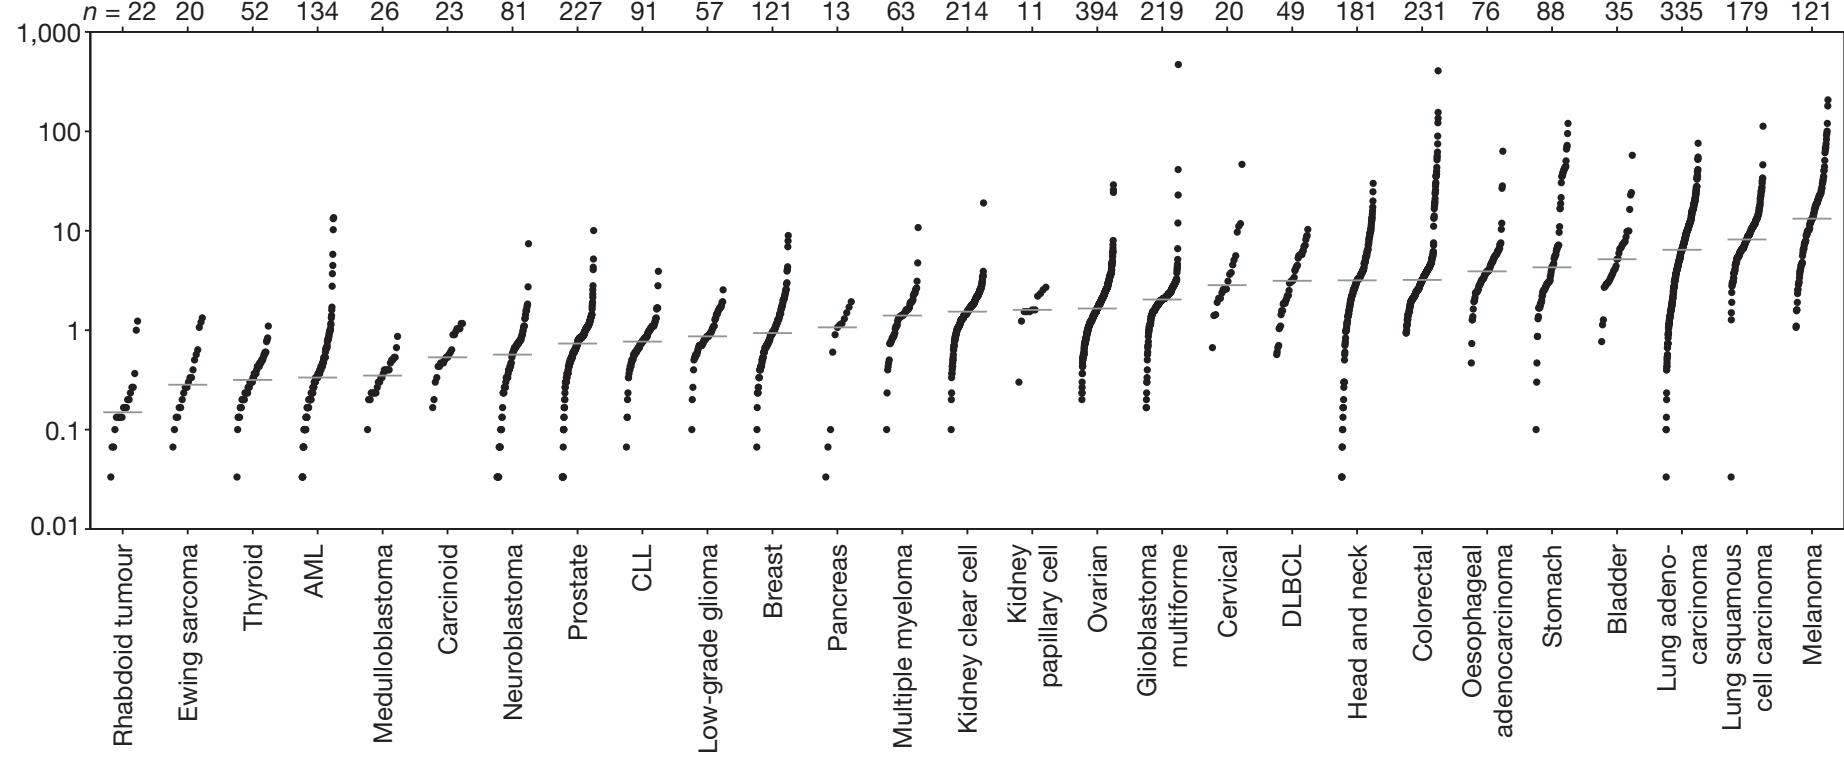

Up to a few dozens of points - just show the data! ([beeswarm](#))

The empirical cumulative distribution function

$$F_n(x) = \frac{\text{number of } i \text{ for which } x_i \leq x}{n} = \frac{1}{n} \sum_{i=1}^n \mathbb{1}(x \leq x_i)$$

```
simdata = rnorm(70)
tibble(index = seq(along = simdata),
       sx = sort(simdata)) %>%
ggplot(aes(x = sx, y = index)) + geom_step()
```

Lander^{1,3,10} & Gad Getz^{1,5}

Impact of non-linear transformation on the shape of a density

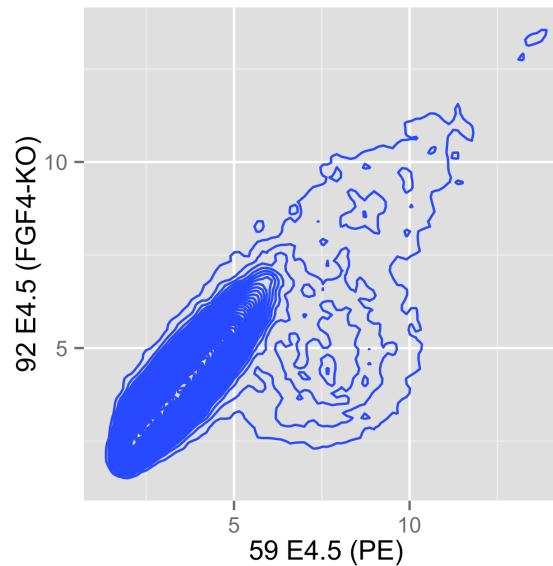

- The mode of a distribution is an infinitesimal concept.
- Need either an infinite amount of data or choose smoothing / binning bandwidth
- Number of modes (let alone their positions) can change under non-linear data transformations

Showing data in 2D

```
scp <- ggplot(dfx, aes( x = '59 E4.5 (PE)' ,  
                      y = '92 E4.5 (FGF4-KO)' ))  
scp + geom_point()
```

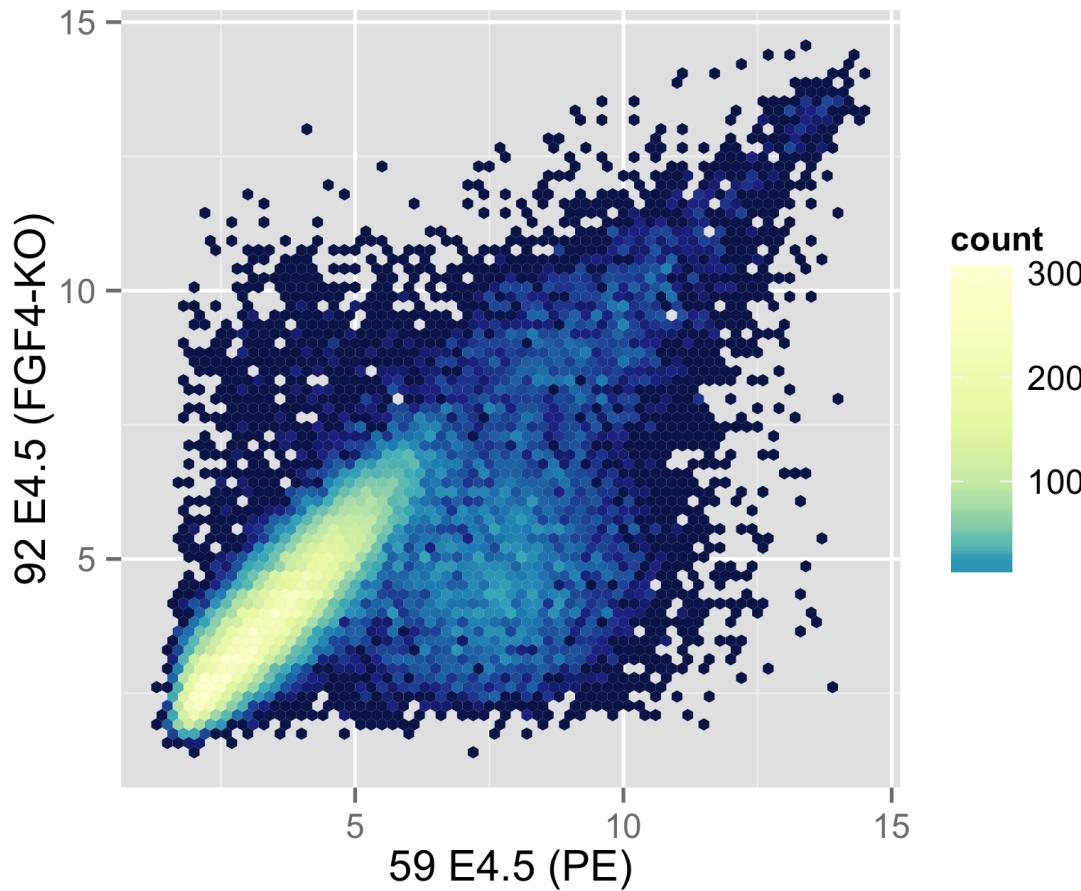

```
scp + geom_point(alpha = 0.1)
```

```
scp + geom_density2d(h = 0.5, bins = 60)
```

Showing data in 2D

```
scp + stat_binhex(binwidth = c(0.2, 0.2)) + colourscale +  
coord_fixed()
```

Yearly sunspot numbers
1849-1924

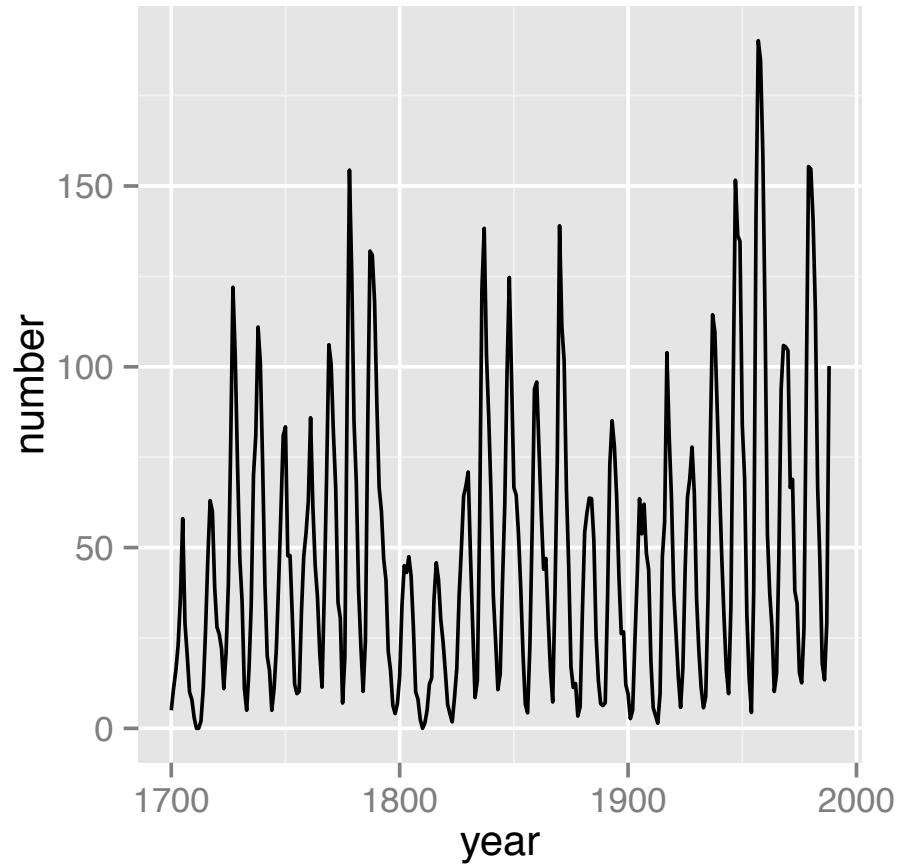

Changes in amplitude

Banking to 45 degrees:

Choose aspect ratio so that
center of absolute values of
slopes is 45 degrees

Sawtooth: Sunspot cycles
typically rise more rapidly than
they fall (pronounced for high
peaks, less for medium and not
for lowest)

Plot shape, banking

Yearly sunspot numbers
1849-1924

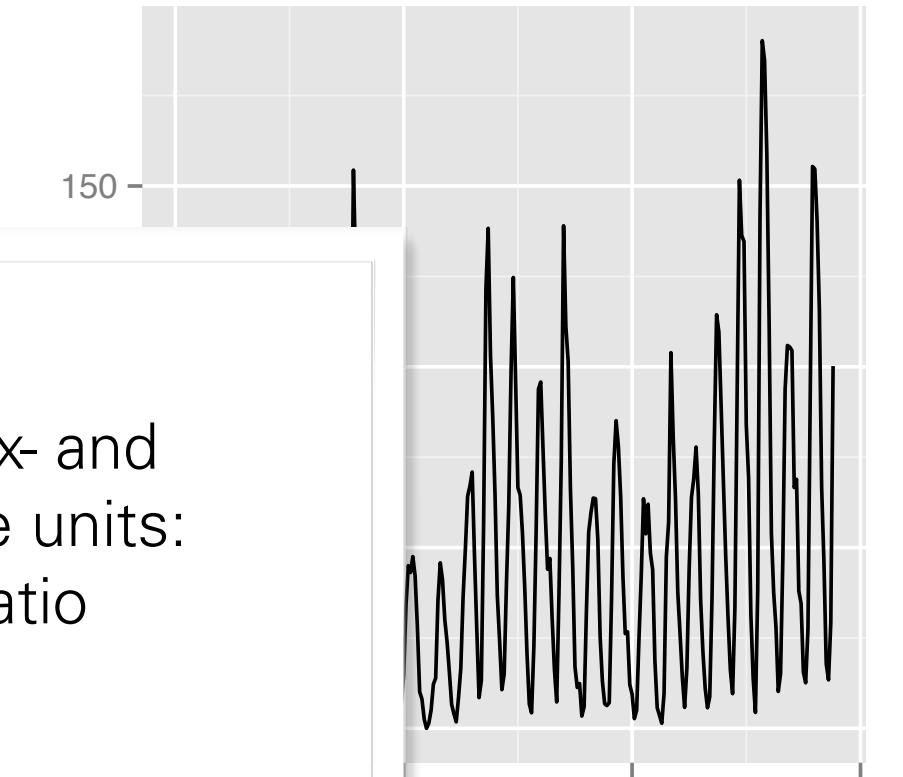

Plot shape, banking

Changes in amplitude

Banking
Choose
center of
slopes is

Sawtooth
typically
they fall (pronounced for high
peaks, less for medium and not
for lowest)

For plots where x- and
y-axis have same units:
use 1:1 aspect ratio
(PCA!)

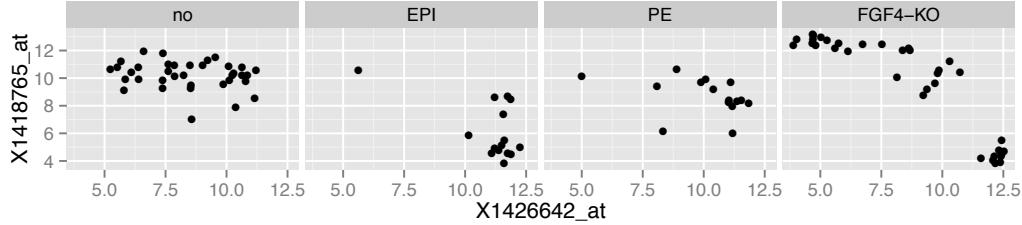

3-5 D and faceting

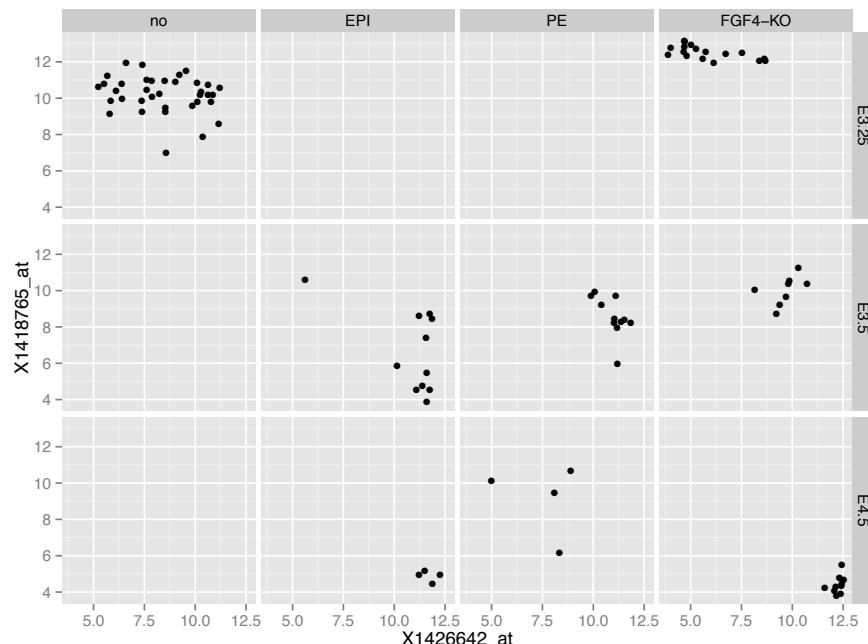

```
ggplot(dftx, aes( x = X1426642_at, y = X1418765_at)) +  
  geom_point() + facet_grid( . ~ lineage )
```

geom_point
offers these
aesthetics
(beyond x and y):

- fill
- colour
- shape
- size
- alpha

```
ggplot( dftx,  
  aes( x = X1426642_at, y = X1418765_at)) + geom_point() +  
  facet_grid( Embryonic.day ~ lineage )
```

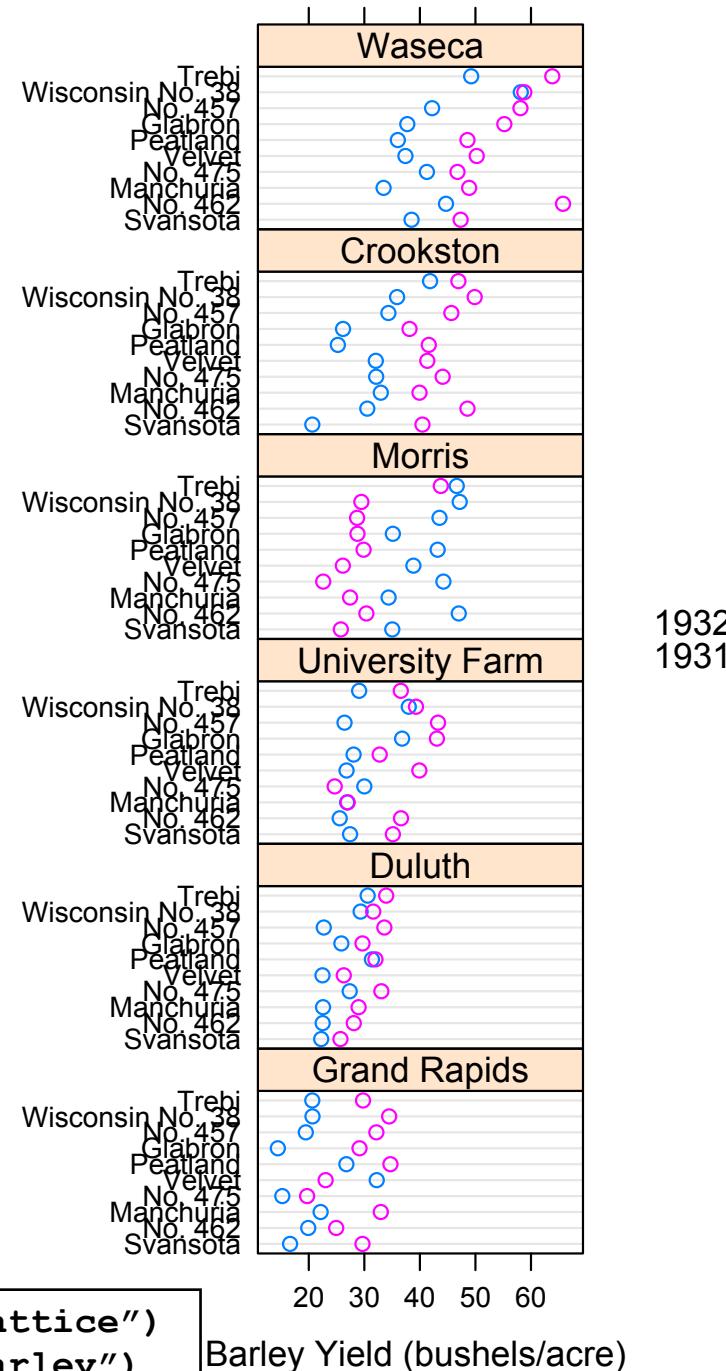

Data from an agricultural field trial to study the crop barley.

At 6 sites in Minnesota, 10 varieties of barley were grown in each of two years.

Data: yield, for all combinations of site, variety, and year ($6 \times 10 \times 2 = 120$ observations)

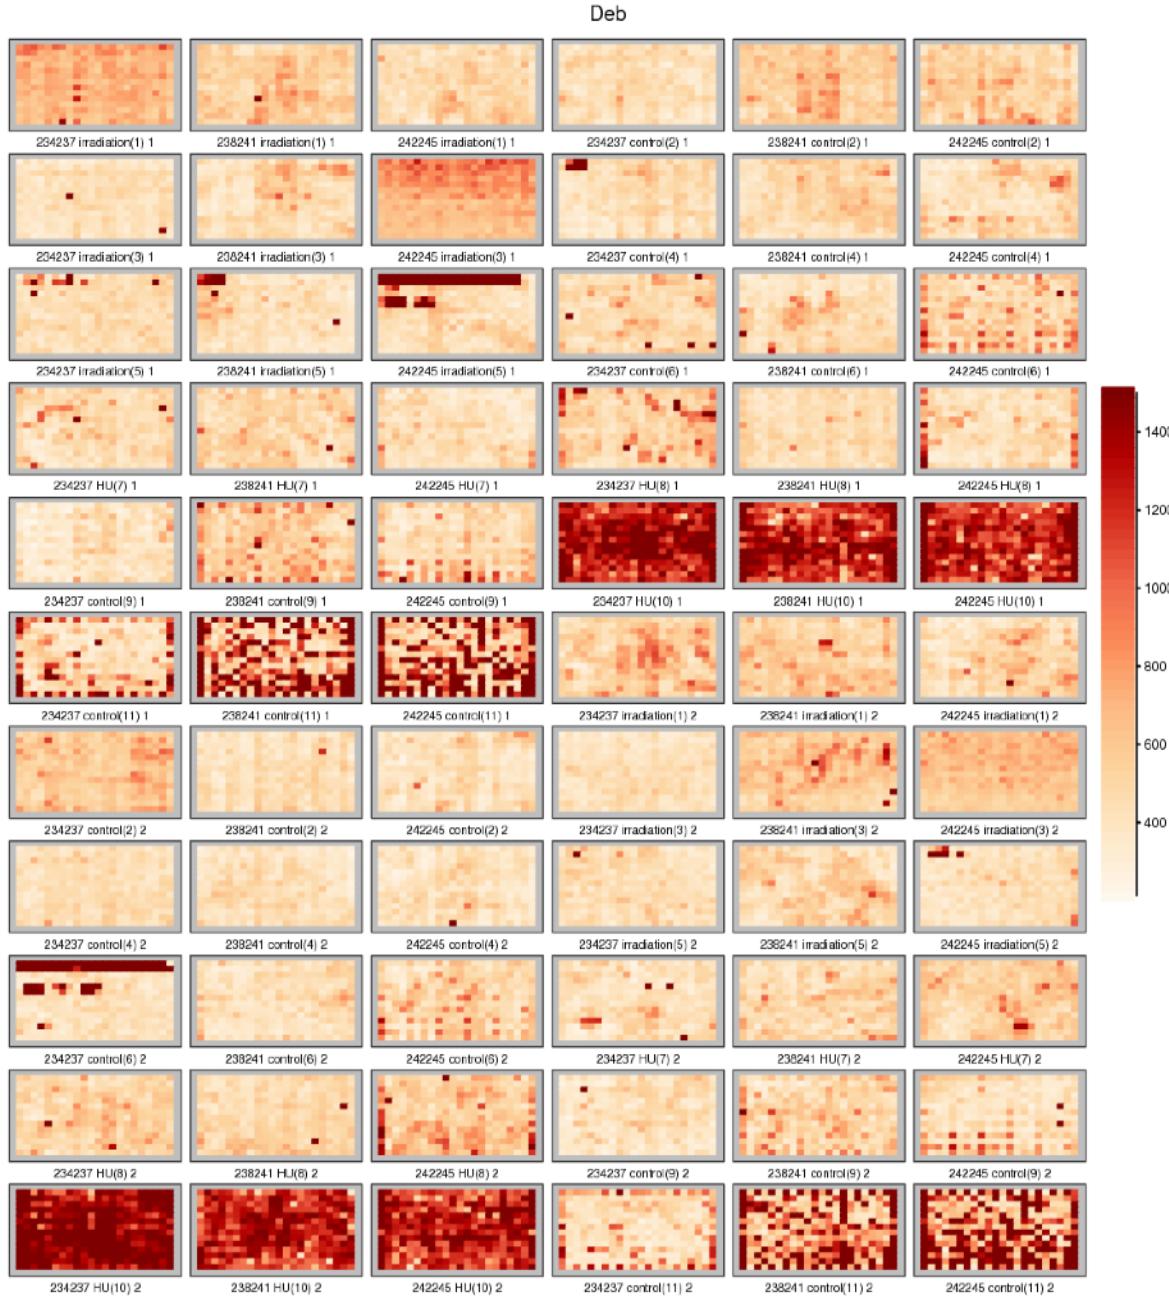

Note the data for Morris - reanalysis in the 1990s using Trellis revealed that the years had been flipped!

```
library("lattice")
example("barley")
```

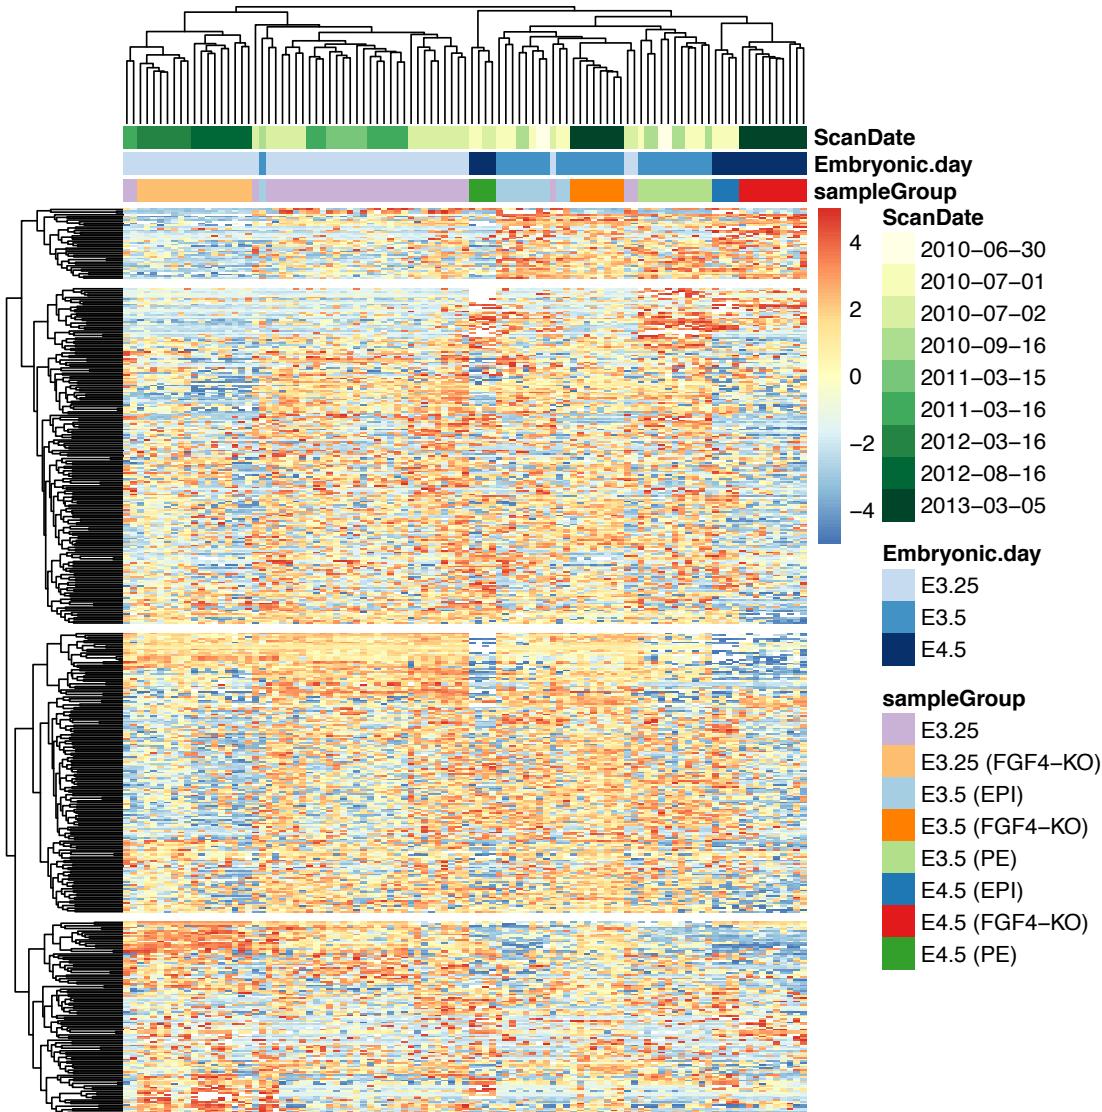

Barley Yield (bushels/acre)

Interactivity

Use shiny or plotly

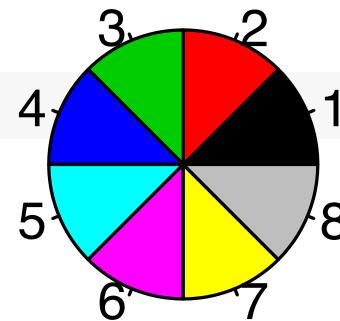

<https://shiny.rstudio.com/gallery/genome-browser.html>

ggvis is dead

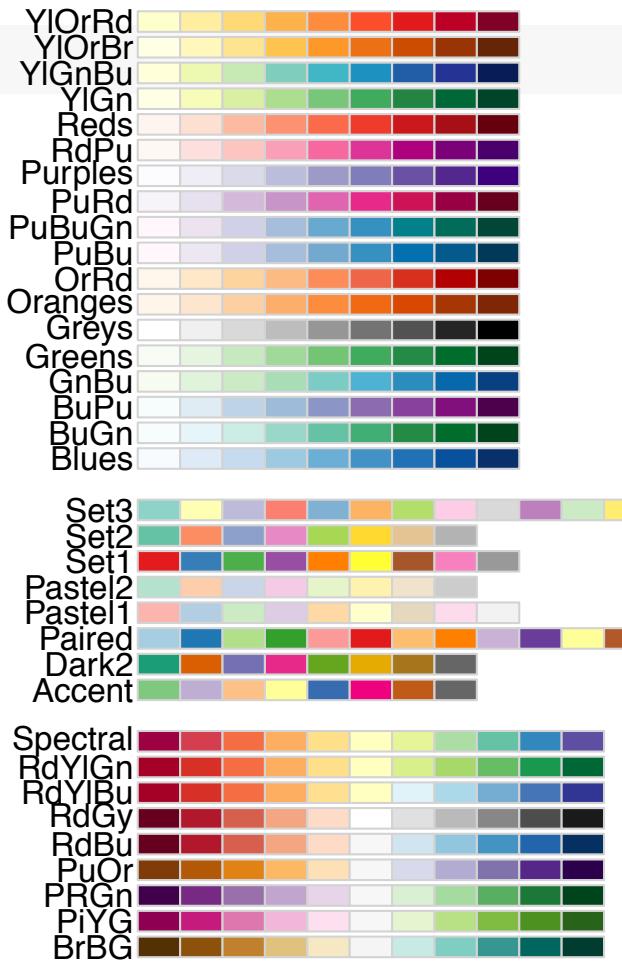

Animations (time-dependent plots):

<https://github.com/thomasp85/gganimate>

```
pie(rep(1, 8), col=1:8)
```

```
display.brewer.all()
```

```
pie(rep(1, 8), c
```

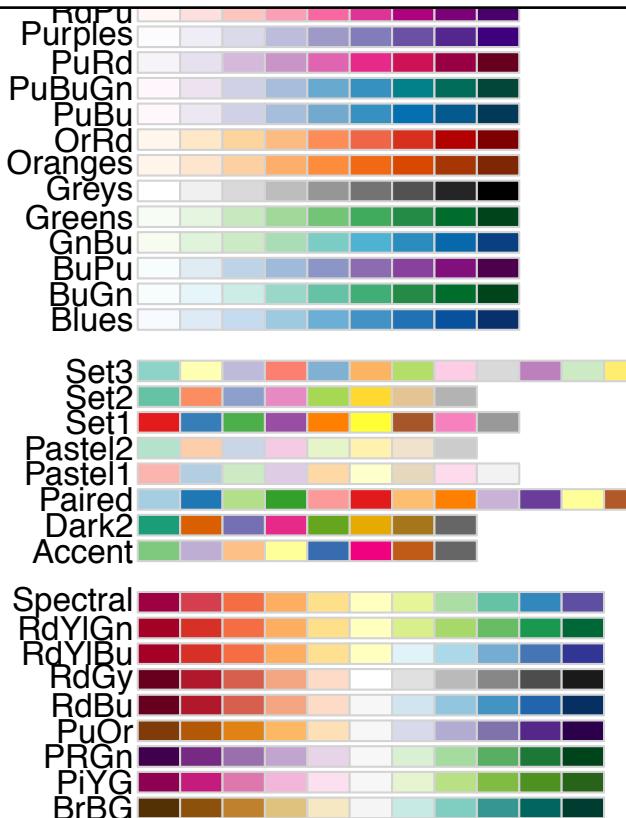

```
display.brewer.
```

Consider these:

Different requirements for line & area colours

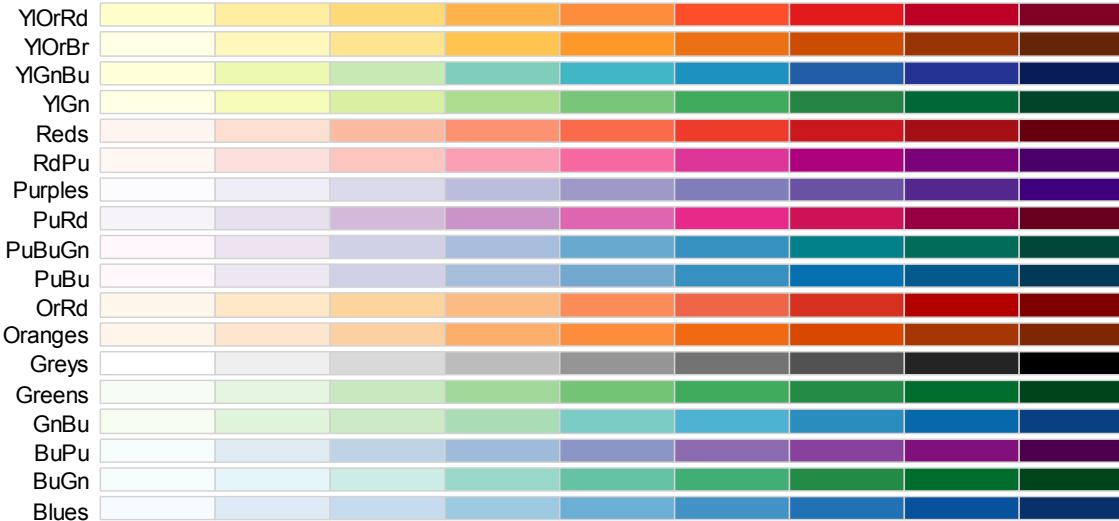

Many people are red-green colour blind

Lighter colours tend to make areas look larger than
darker colours → use colors of equal luminance for
filled areas.

qualitative

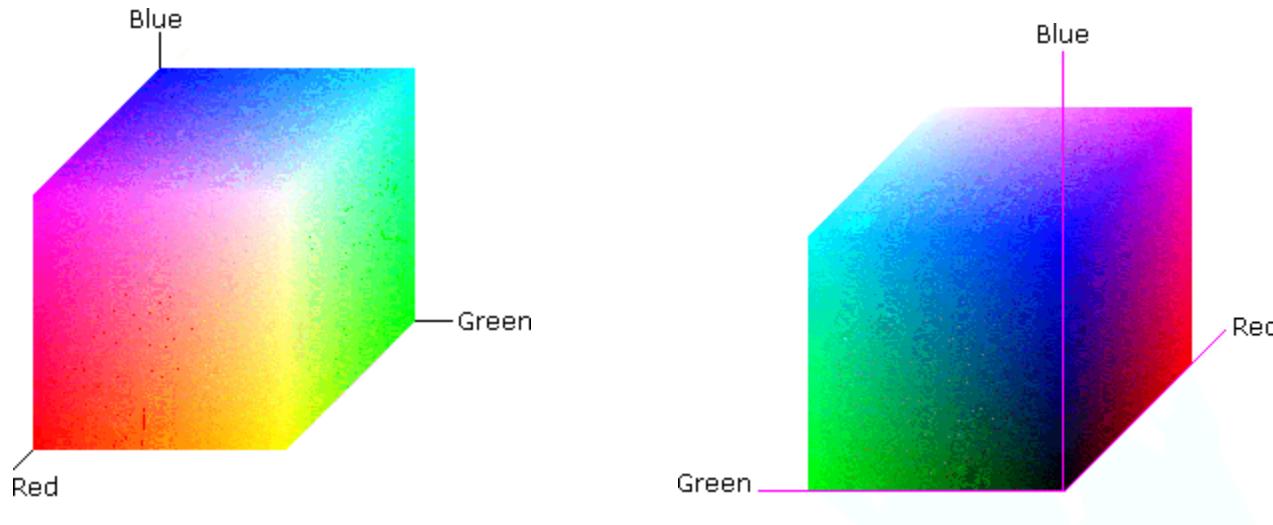

diverging

RGB color space

Motivated by computer screen hardware

HSV color space

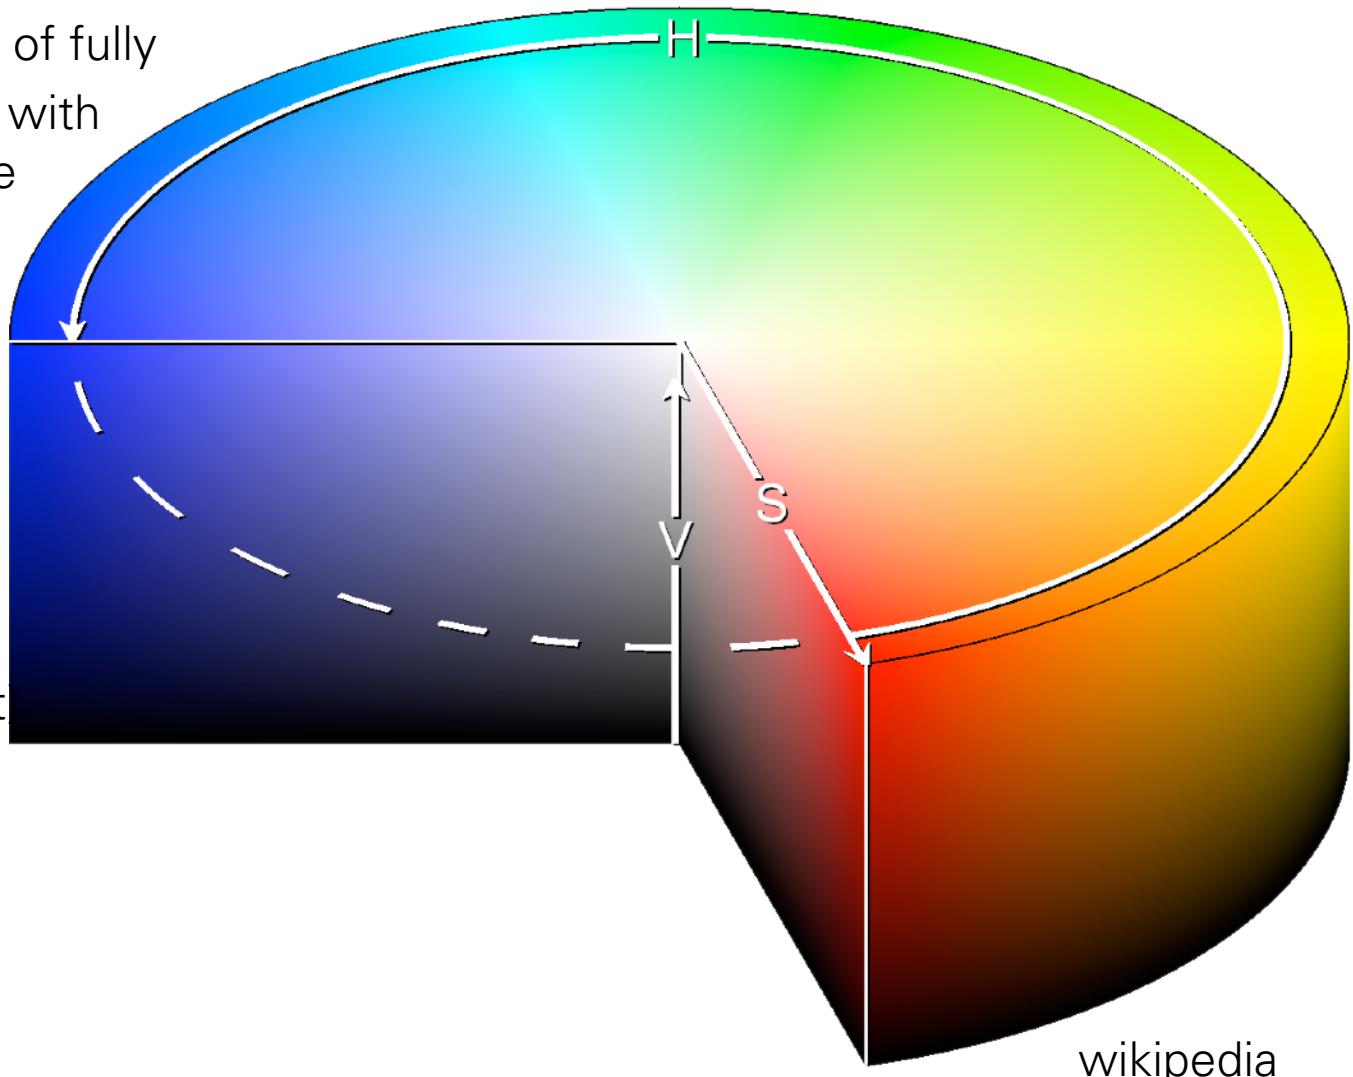

Hue-Saturation-Value (Smith 1978)

V_{\max} : a planar area of fully saturated colours, with white in the centre

hue: similarity to a primary color

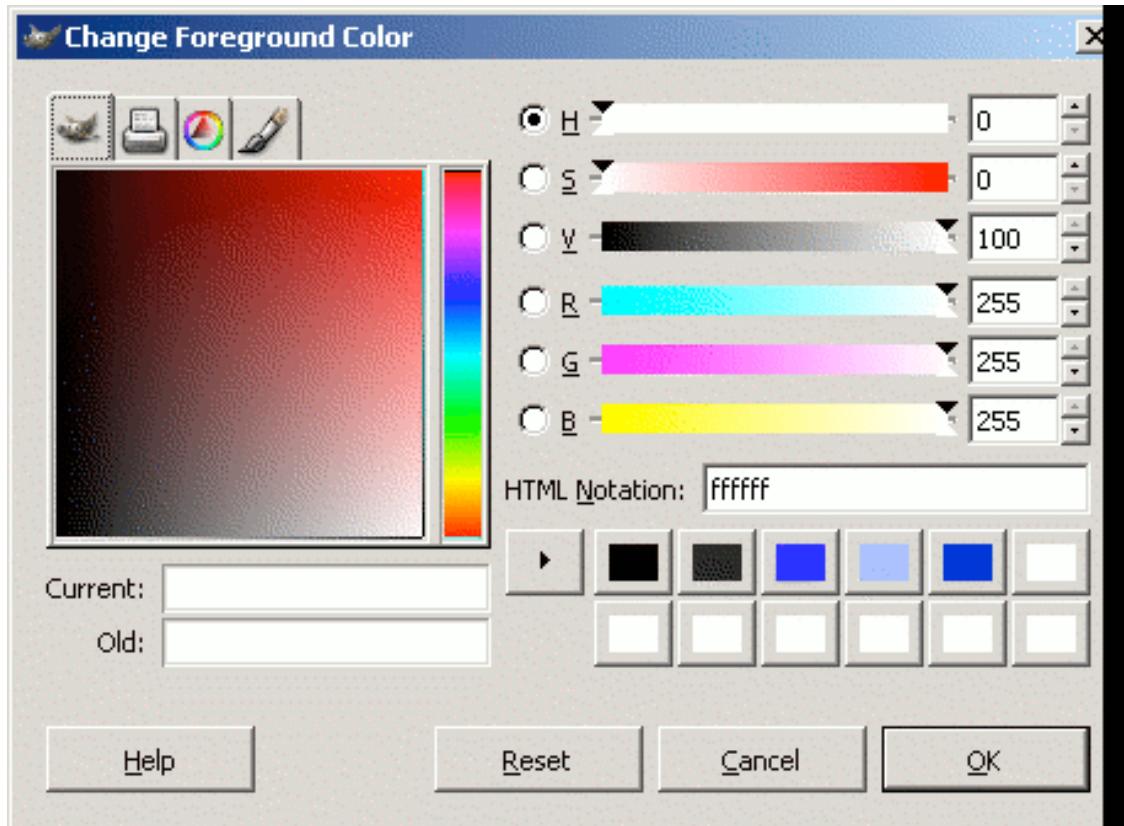

saturation: width of the spectral distribution

V_{\min} : black (one point)

HSV color space

GIMP colour selector

linear or circular hue
chooser

and

a two-dimensional
area (usually a square
or a triangle) to choose
saturation and value/
lightness for the
selected hue

(almost) 1:1 mapping between RGB and HSV space

Conversion from RGB to HSL or HSV

Let $r, g, b \in [0, 1]$ be the red, green, and blue coordinates, respectively, of a color in RGB space.

Let \max be the greatest of r, g , and b , and \min the least.

To find the hue angle $h \in [0, 360]$ for either HSL or HSV space, compute:

$$h = \begin{cases} 0 & \text{if } \max = \min \\ (60^\circ \times \frac{g-b}{\max - \min} + 0^\circ) \bmod 360^\circ, & \text{if } \max = r \\ 60^\circ \times \frac{b-r}{\max - \min} + 120^\circ, & \text{if } \max = g \\ 60^\circ \times \frac{r-g}{\max - \min} + 240^\circ, & \text{if } \max = b \end{cases}$$

To find saturation and lightness $s, l \in [0, 1]$ for HSL space, compute:

$$s = \begin{cases} 0 & \text{if } \max = \min \\ \frac{\max - \min}{\max + \min} = \frac{\max - \min}{2l}, & \text{if } l \leq \frac{1}{2} \\ \frac{\max - \min}{2 - (\max + \min)} = \frac{\max - \min}{2 - 2l}, & \text{if } l > \frac{1}{2} \end{cases}$$

$$l = \frac{1}{2}(\max + \min)$$

wikipedia

The value of h is generally normalized to lie between 0 and 360° , and $h = 0$ is used when $\max = \min$ (that is, for grays) though the hue has no geometric meaning there, where the saturation s is zero. Similarly, the choice of 0 as the value for s when l is equal to 0 or 1 is arbitrary.

HSL and HSV have the same definition of [hue](#), but the other components differ. The values for s and v of an HSV color are defined as follows:

$$s = \begin{cases} 0, & \text{if } \max = 0 \\ \frac{\max - \min}{\max} = 1 - \frac{\min}{\max}, & \text{otherwise} \end{cases}$$

$$v = \max$$

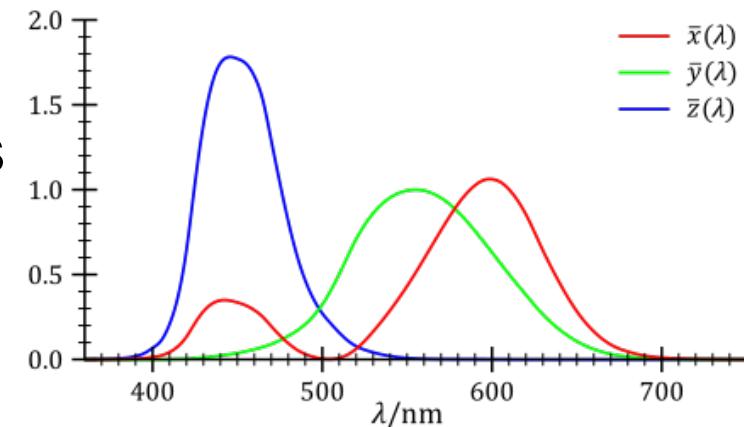

The range of HSV and HSL vectors is a cube in the [cartesian coordinate system](#); but since hue is really a cyclic property, with a cut at red, visualizations of these spaces invariably involve hue circles.^[4] [cylindrical](#) and conical (bi-conical for HSL) depictions are most popular; [Spherical](#) depictions are also possible.

Perceptual colour spaces

Human perception of colour corresponds neither to RGB nor HSV coordinates, and neither to the physiological axes light-dark, yellow-blue, red-green

Perceptually based coordinates of colour space: CIELUV, CIELAB

Commission Internationale de l' Éclairage (CIE) in 1931, on the basis of extensive colour matching experiments with people, defined a "standard observer" who represents a typical human colour response (response of the three light cones + their processing in the brain) to a triplet (x,y,z) of primary light sources

https://en.wikipedia.org/wiki/CIE_1931_color_space

1976: CIELUV (L , u , v)-coordinates are preferred by those who work with emissive colour technologies (e.g. computer displays); CIELAB by those working with dyes and pigments (such as in the printing and textile industries)

HCL colours

$$(u,v) = \text{chroma} * (\cos h, \sin h)$$

L the same as in CIELUV, (C, H)
are simply polar coordinates for
(u,v)

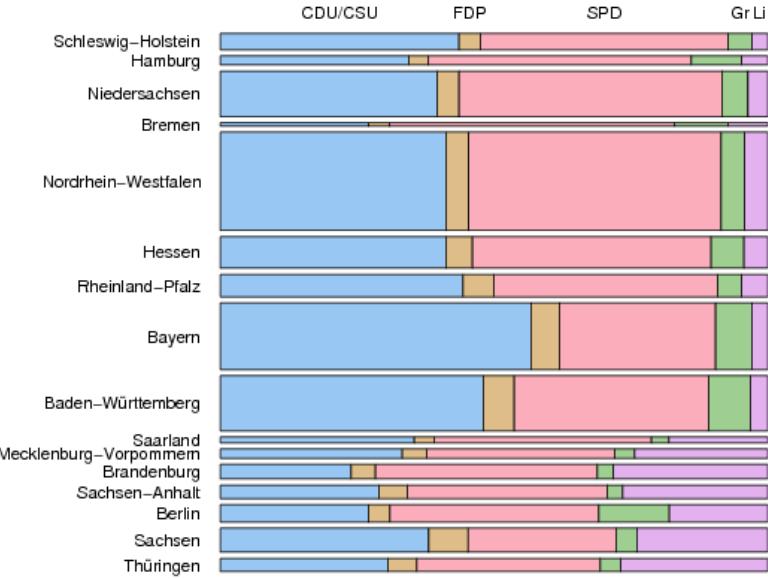

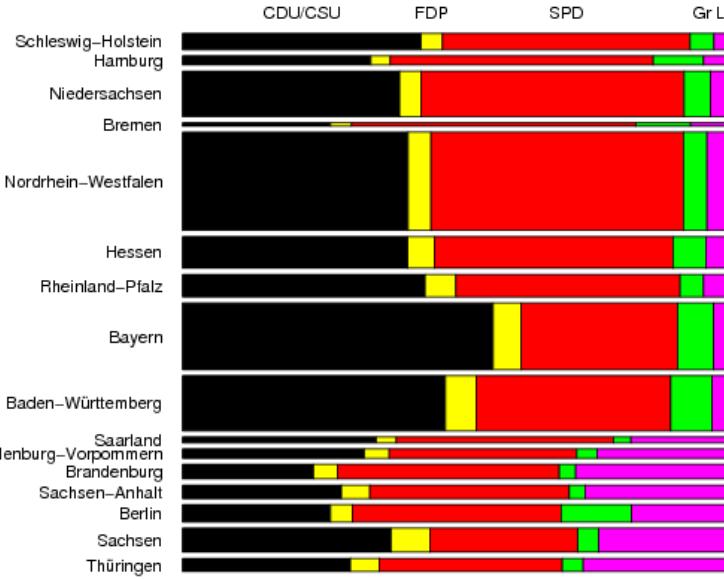

1. hue (dominant wavelength)
2. chroma (colorfulness, intensity of color as compared to gray)
3. luminance (brightness, amount of gray)

a**b**

Figure 2: Circles in HCL colorspace. *a*: circles in HCL space at constant $L = 75$, with the angular coordinate H varying from 0 to 360 and the radial coordinate $C = 0, 10, \dots, 60$. *b*: constant $C = 50$, and $L = 10, 20, \dots, 90$.

Pick your favourite

From A. Zeileis, Reisenburg 2007

Balance

The intensity of colour which should be used is dependent on the area that that colour is to occupy. Small areas need to be more colourful than larger ones.

Choose colours centred on a mid-range or neutral value, or;

Choose colours at equally spaced points along smooth paths through (perceptually uniform) colour space: equal luminance and chroma and correspond to set of evenly spaced hues.
